PRACTICAL – 7

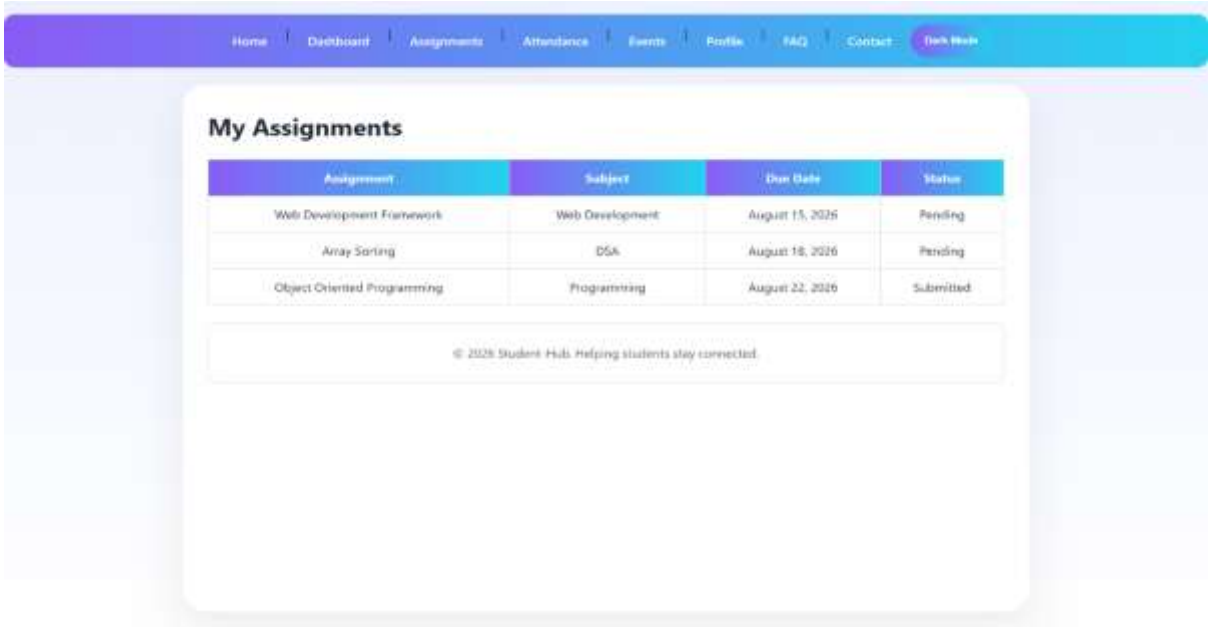

Problem Definition: Process submitted registration/contact form data using PHP. Validate and sanitize inputs on the server side and store records in CSV or JSON file format. Display success/error messages.

Frequently Asked Questions
How can I register as a student?
Where can I see upcoming events?
Can I search for a specific event?
Can I filter events by category?
Can I sort the event list?
Where can I view student profiles?
Can I search students?
Can the same data loader be reused?

Question & Answer:

1. Is the form submitted using POST?

Yes, the registration form is submitted using the POST method through the PHP file. The method="POST" attribute sends form data securely to the server without displaying it in the URL. PHP receives the submitted values using the $_POST variable. The data is then processed and validated on the server. This makes the form suitable for secure server-side processing.

2. Are inputs validated and sanitized server side?

Yes, all important inputs are validated and sanitized on the server side using PHP. The code checks the name, email, mobile number, course, year, gender, password, and other required fields. Functions such as trim() and filter_var() are used to clean and validate the input data. Regular expressions are also used for specific formats such as mobile numbers and passwords. This provides an additional security layer beyond client-side JavaScript validation.

3. Is file writing handled safely?

Yes, the submitted registration data is stored safely in a CSV file using PHP file-handling functions. The program creates the required data folder and CSV file when necessary. File locking using flock() helps prevent conflicts when multiple records are written at the same time. The file is opened, written, unlocked, and closed properly. Passwords are not stored in the CSV file, which improves the security of the stored data.

4. Are success and error responses displayed clearly?

Yes, the PHP program displays clear success and error messages after form submission. If the information is valid, a success message confirms that the registration has been stored successfully. If any input is invalid, an appropriate error message explains what needs to be corrected. The messages are displayed clearly on the registration page. This provides useful feedback and makes the form easier for users to understand.

Conclusion / Learning Outcome:

In this practical, PHP was used to process registration form data on the server side. The form data was submitted using the POST method and validated before processing. Input values were sanitized to improve security and prevent invalid data from being stored. The validated records were safely stored in a CSV file using PHP file-handling techniques. Clear success and error messages were displayed to provide proper feedback to the user. This practical helped in understanding server-side form processing and safe file-based data storage. Overall, the practical demonstrated how PHP can be used to build reliable and secure backend form-processing systems.
