Question & Answer:

1. Is the schema normalized properly?

Yes, the database schema is properly normalized to avoid unnecessary data duplication. The students, events, and registrations data are stored in separate tables. Each table contains information related to its own purpose. The registrations table connects students and events using their IDs. This structure makes the database organized, consistent, and easier to maintain.

2. Are primary keys and foreign keys correctly defined?

Yes, primary keys and foreign keys are correctly defined in the database. student_id is the primary key of the students table, while event_id is the primary key of the events table. registration_id is the primary key of the registrations table. The student_id and event_id in registrations are foreign keys that maintain proper relationships between the tables.

3. Is the database connection handled securely?

Yes, the database connection is handled using basic MySQLi with proper error handling. The connection details are kept in a separate db.php file instead of repeating them throughout the project. Prepared statements are used for operations involving user input to reduce the risk of SQL injection. Input validation and htmlspecialchars() are also used where appropriate.

Conclusion / Learning Outcome:

The StudentHub database was successfully designed using a normalized MySQL schema containing students, events, and registrations tables.
The schema reduces data duplication and maintains proper relationships between the tables.
Primary keys uniquely identify records, while foreign keys maintain referential integrity between students, events, and registrations.
Prepared statements were used for database operations involving user input to improve security and prevent SQL injection.
The database was tested using phpMyAdmin and XAMPP with sample student, event, and registration data.
Overall, the practical demonstrates the design of a secure and reliable database-backed web application.
